# **Informe Tarea 2**

Luis Ramírez Donoso

La tarea  $N^{\circ}$  2 de Sistemas Recomendadores se basa en la implementación de un algoritmo que pueda recomendar artículos en base a contenidos, es decir, utilizar Content Based Recommender.

La tarea en particular cuenta de 4 actividades.

#### 1.- Leer en el data

Consiste en extender 2 clases, agregando dos columnas del archivo de entrada. Los campos son título y descripción. Las clases involucradas en esta modificación son common/Bookmark y file/BookmarkReader.

# Dentro de common/Bookmark

```
public class Bookmark implements Comparable<Bookmark> {
     private int userID;
     private int resID;
     private String timestamp;
     private List<Integer> tags;
     private double rating;
     private List<Integer> categories;
     private String title;
     private String description;
     public Bookmark(int userID, int wikiID, String timestamp,
String title,String description) {
          this.userID = userID;
          this.resID = wikiID;
          this.timestamp = timestamp;
          this.title = title;
          this.description = description;
          this.rating = -2.0;
          this.categories = new ArrayList<Integer>();
```

```
this.tags = new ArrayList<Integer>();
     }
     @Override
     public int compareTo(Bookmark data) {
          //return (Long.parseLong(getTimestamp()) <=</pre>
Long.parseLong(data.getTimestamp()) ? - 1 : 1);

*/ }
                      title = lineParts[6].replace("\"", "");
```

## 2.- Implemetar un Tag recomendador basado en contenido

Para esta tarea fue muy difícil lograr implementar. Se realizó un estudio del lenguaje JAVA para entender su sintaxis y estructura. Luego se realizó una investigación de sistemas similares que realizaran algún cálculo para lograr recomendar ítem en base a contenido. Fue muy difícil encontrar, pero lo más difícil fue lograr interpretar para incluirlo en el código de la clase a la cual se debía modificar.

La clase que se debía tocar es processing/ContentBasedCalculator y el método dentro de esta clase es getRankedTagList.

Se logró implementar un cálculo de comparación como se presenta en el siguiente código de la clase:

```
public class ContentBasedCalculator {
    private final static int REC_LIMIT = 10;

    private BookmarkReader reader;
    private List<Bookmark> trainList;

    private List<Map<Integer, Double>> userMaps;
    private List<Map<Integer, Double>> tagRecencies;
    private List<Map<Integer, Double>> resMaps;
```

```
public ContentBasedCalculator(BookmarkReader reader, int
trainSize) {
           this.reader = reader;
           // TODO: use this data for recommendations
           this.trainList =
this.reader.getBookmarks().subList(0, trainSize);
     public Map<Integer, Double> getRankedTagList(int userID,
int resID) {
           Map<Integer, Double> resultMap = new
LinkedHashMap<Integer, Double>();
           this.tagRecencies = new ArrayList<Map<Integer,</pre>
Double>>():
           // TODO: calculate your recommendations here and
return the top-10 (=REC_LIMIT) tags with probability value
           // have also a look on the other calculator classes!
                if (this.userMaps != null && userID <</pre>
this.userMaps.size()) {
                      Map<Integer, Double> userMap =
this.userMaps.get(userID);
                      Map<Integer, Double> recMap =
this.tagRecencies.get(userID);
                      for (Map.Entry<Integer, Double> entry :
userMap.entrySet()) {
                           resultMap.put(entry.getKey(),
entry.getValue().doubleValue() *
recMap.get(entry.getKey()).doubleValue());
                if (this.resMaps != null && resID <</pre>
this.resMaps.size()) {
                      Map<Integer, Double> resMap =
this.resMaps.get(resID);
                      for (Map.Entry<Integer, Double> entry :
resMap.entrySet()) {
                           Double val =
resultMap.get(entry.getKey());
                           resultMap.put(entry.getKey(), val ==
null ? entry.getValue().doubleValue() : val.doubleValue() +
```

```
entry.getValue().doubleValue());
                }
                Map<Integer, Double> returnMap = new
LinkedHashMap<Integer, Double>();
                Map<Integer, Double> sortedResultMap = new
TreeMap<Integer, Double>(new DoubleMapComparator(resultMap));
                sortedResultMap.putAll(resultMap);
                int count = 0;
                for (Map.Entry<Integer, Double> entry :
sortedResultMap.entrySet()) {
                      if (count++ < 10) {
                           returnMap.put(entry.getKey(),
entry.getValue());
                     } else {
                           break;
                     }
                }
                return returnMap;
En ésta base del código comentado, se deja en evidencia el
cálculo de la recomendación en base a la estrategia utilizada TF-
IDF, utilizando el coseno del item y del perfil del usuario.
//Ahora calculo en base a TF-IDF
```

```
// DecimalFormat df = new DecimalFormat("0.0000");

// Obtener el perfil del usuario con el "Me

Gusta" para cada etiqueta

//SparseVector userVector =

makeUserVector(userID);

// Loop sobre cada elemento requerido y su

puntuación

// El dominio del vector de salida es lo que se

conseguirá
```

```
//for (VectorEntry e:
resID.fast(VectorEntry.State.EITHER))
                //{
                      // El Score <u>del</u> item <u>representado</u> <u>por</u> e.
                      // Obtener el vector del item para este
item en particular
                //
                      SparseVector iv =
model.getItemVector(e.getKey());
                      // <u>Se calcula</u> el <u>coseno</u> <u>del</u> item y el
perfil del ususario
                      //Se guarda en el vector de salida
                     double numerator = iv.dot(userVector);
                // double denominator = iv.norm() *
userVector.norm();
                // double cosineSimilarity = numerator /
denominator;
                // try
                // {
                //
                            double rounded =
df.parse(df.format(cosineSimilarity)).doubleValue();
                           logger.info("Cos similarity for item
{} and user {} is {}", e.getKey(), userID, rounded);
                //
                            resID.set(e.getKey(), rounded);
                // catch (ParseException e1)
                           logger.error("Error while parsing
double", e1);
                //
     public static List<Map<Integer, Double>>
startContentBasedCreation(BookmarkReader reader, int sampleSize)
{
           int size = reader.getBookmarks().size();
           int trainSize = size - sampleSize;
```

```
ContentBasedCalculator calculator = new
ContentBasedCalculator(reader, trainSize);
           List<Map<Integer, Double>> results = new
ArrayList<Map<Integer, Double>>();
           if (trainSize == size) {
                trainSize = 0;
           }
           for (int i = trainSize; i < size; i++) { // the test-</pre>
set
                Bookmark data = reader.getBookmarks().get(i);
                Map<Integer, Double> map =
calculator.getRankedTagList(data.getUserID(), data.getWikiID());
                results.add(map);
           return results;
     }
     public static void predictSample(String filename, int
trainSize, int sampleSize) {
           BookmarkReader reader = new BookmarkReader(trainSize,
false);
           reader.readFile(filename);
           List<Map<Integer, Double>> modelValues =
startContentBasedCreation(reader, sampleSize);
           List<int∏> predictionValues = new
ArrayList<int[]>();
           for (int i = 0; i < modelValues.size(); i++) {</pre>
                Map<Integer, Double> modelVal =
modelValues.get(i);
     predictionValues.add(Ints.toArray(modelVal.keySet()));
           String suffix = "_cb";
     reader.setUserLines(reader.getBookmarks().subList(trainSize
, reader.getBookmarks().size()));
           PredictionFileWriter writer = new
PredictionFileWriter(reader, predictionValues);
           String outputFile = filename + suffix;
           writer.writeFile(outputFile);
```

```
}
```

## 3.- Evaluación del Tag Recomendador

El resultado del tag implementado es posible comprobar su funcionamiento al editar en el archivo pipeline la línea de código asociada a la ejecución del método.

El resultado es depositado queda registrado en la ruta data/metrics/bib core y el archivo TXT se llama "cb\_metrics\_avg.txt".

El resultado se arroja como sigue:

```
